

Appendix A - Table A2. Summary of appropriate [study design](#), [camera spacing](#), and [survey](#) effort (adapted from Wearn & Glover-Kapfer [2017] with additional references included) for various [modelling approaches](#). Note – these are guidelines only, using best available information. There is uncertainty associated with each of the different approaches. To address this, the table contains ‘minimum’, ‘ideal’ and ‘often’ used values, as well as qualifiers.

Approach	Camera arrangement	Camera spacing	Number of cameras	Camera days per camera location	Total number of camera days	Survey duration	References

- ⁱ **Camera spacing to achieve spatial independence for species diversity and richness:** locations should be independent, meaning that any two locations do not sample the same community of animals. Note - this may be hard to achieve when considering the movement distances of some species, such as big cats, and in practice, a [camera spacing](#) of 1-2 km is often used (e.g., Tobler et al., 2008; Ahumada et al., 2011; Kinnaird & O'Brien, 2012)
- ⁱⁱ **Number of cameras for occupancy models:** should be based on expected occupancy probability (i.e., the expected probability that a given camera site is occupied, for a given species [Kays et al., 2020]).
- ⁱⁱⁱ **Paired design camera arrangement for CR:** due to the higher chance of recognizing all individuals captured in a [survey](#); using two cameras also decreases the chances of missing captures entirely (Tobler et al., 2008).
- ^{iv} **Targeted camera arrangement for CR:** This design is commonly used when estimating densities of [marked populations](#) (e.g., [spatially explicit capture-recapture \[SECR\]](#); Borchers & Efford, 2008; Efford, 2004; Royle & Young, 2008]) or behaviour studies. However, [targeted](#) sampling may impede the ability to draw inferences beyond the [survey](#) area (Wearn & Glover-Kapfer, 2017).
- ^v **Camera spacing to achieve spatial dependence for CR:** "[camera locations](#) should be sufficiently close to one another such that individuals are picked up across more than one location" (Wearn & Glover-Kapfer, 2017).
- ^{vi} **Camera spacing should be species-dependent (home range size) for CR/CMR:** There is a trade-off between [density](#) and [survey](#) extent: 10-30 individuals exposed with a [camera location](#) density of at least 2-4 per smallest home range.
- ^{vii} **Ideally, systematic camera arrangement, closely spaced cameras for [2-flank SPIM](#):** due to the increased likelihood of capturing both sides of the animal (Augustine et al., 2018)
- ^{viii} **Fewer number of cameras [2-flank SPIM](#) than for [SCR](#) (or same but larger sample area):** Note - larger sampling areas preferred for [2-flank SPIM](#) since there will be fewer samples collected on the periphery of the sampled area and thus less uncertainty in identifying individuals (Augustine et al., 2018).
- ^{ix} **Random camera arrangement for [REM](#):** Note that species with very restricted distributions in a landscape are best sampled using a [stratified design](#) (Wearn & Glover-Kapfer, 2017).
- ^x **Systematic random camera arrangement for [REM](#):** to ensure a minimum separation between cameras (Wearn & Glover-Kapfer, 2017).
- ^{xi} **Stratified targeted camera arrangement for [REM](#):** species that are highly restricted in occurrence (Wearn & Glover-Kapfer, 2017).
